ACID SENSITIVITY SURVEY OF LAKES IN ONTARIO — 1989

Background

One of the most pressing environmental problems facing large areas of North America is acidic precipitation. All of southern Ontario receives a steady bombardment of acids, acid forming gases and associated pollutants. The acids come down with rain, snow, fog, and small particles in the air.

Man's activities are responsible for the large majority of these acids. Smelters and coal-fired electric generating stations both in Canada and the United States spew millions of tonnes of sulphur dioxide into the atmosphere annually. Cars, trucks, and trains contribute more millions of tonnes of nitrogen oxides. These gases react with sunlight, oxygen, ozone, water and other gases to form sulphuric and nitric acid — strong, corrosive acids.

In unpolluted areas, rain and snow are naturally slightly acidic since carbon dioxide which is a natural component of the atmosphere, dissolves in water to form weak carbonic acid. Water quality of lakes has developed in response to weathering processes induced by this weak acid. Rocks and minerals react with carbonic acid to form bicarbonate, which is found in natural waters everywhere.

The complex biological communities in lakes, streams and forests have adapted and evolved in equilibrium with these natural conditions and processes. However, acid rain has seriously disturbed this equilibrium.

Levels of Acidity

The acidity of a solution is measured on a pH scale. The pH scale is termed logarithmic. This means that a change of one unit on the pH scale corresponds to a ten-fold increase or decrease in acidity. Thus, a solution with a pH of 4.0, is ten times more acidic than a solution of pH 5.0, and one hundred times more acidic than a solution with a pH of 6.0.

Distilled water is considered to be neither acidic or alkaline, and has a pH of 7.0. The carbon dioxide in the atmosphere will cause rain to have a pH of about 5.6 if no other factors are affecting the pH.

Rainfall with a pH less than 5.6 is termed "acid rain," but significant amounts of acid are also deposited as gases and particles through processes called "dry deposition." Over most of southern Ontario, the average pH of the rain is about 4.2. In the remote northwest, the average pH is above 5.0. Because acid deposition is higher in southern Ontario than in the northern parts, more acid lakes are found in the south.

Survey of Lakes

There are over 250,000 lakes in Ontario. Of these, a recent study indicates at least 19,000 have been affected by acid rain, many of them in the Muskoka-Haliburton region, where there is a substantial cottage and tourist industry.

Most lakes have the ability to neutralize a certain amount of acid. This neutralizing capacity of a lake is measured by the level of bicarbonate alkalinity in the water. If a lake has a high alkalinity level, it can resist pH changes caused by acid inputs. Lakes with low alkalinities can experience pH depressions during spring snowmelt or after heavy rains, times when large acid loads enter the lakes.

A lake with zero or less alkalinity is an acid lake. A negative reading of alkalinity means that the lake contains mineral acidity. These lakes usually have a pH less than 5.0, and if they have any fish at all, it will be a hardy, acid-tolerant species like yellow perch. As a lake acidifies, sensitive species such as bass and trout will probably not reproduce, although some adult fish may still survive until they die of old age or other causes.

The neutralizing capacity of a lake is dependent on a number of factors. Lakes in limestone regions usually have a very high alkalinity, since bicarbonate alkalinity results

ÉTUDE DE LA SENSIBILITÉ DES LACS DE L'ONTARIO AUX DÉPÔTS ACIDES — 1989

Historique

Les précipitations acides sont au nombre des problèmes environnementaux les plus importants de vastes régions de l'Amérique du Nord. Tout le Sud de l'Ontario est continuellement exposé à des acides, des gaz qui se transforment en acides et d'autres polluants connexes. On doit les dépôts acides à la pluie, à la neige, au brouillard et aux particules en suspension dans l'air lorsqu'ils tombent au sol.

On doit la plus grande partie de ces acides aux activités humaines. Tant au Canada qu'aux États-Unis, les fonderies et les centrales alimentées au charbon rejettent chaque année dans l'atmosphère des millions de tonnes d'anhydride sulfureux. Les voitures, les camions et les trains produisent des millions de tonnes supplémentaires d'oxydes d'azote. Ces gaz réagissent avec la lumière solaire, l'oxygène, l'ozone, l'eau et d'autres gaz pour former de l'acide nitrique et de l'acide sulfurique, qui sont des acides forts et corrosifs.

Dans les régions non polluées, la pluie et la neige sont légèrement acides à l'état naturel, car le gaz carbonique est un composant naturel de l'atmosphère, qui se dissout dans l'eau pour former un acide carbonique faible. L'eau des lacs à l'état naturel atteste du processus chimique qu'engendre la présence de cet acide faible. Les roches et les minéraux réagissent avec l'acide carbonique pour former du bicarbonate que l'on trouve partout dans l'eau à l'état naturel.

Les espèces biologiques complexes qui peuplent les lacs, cours d'eau et forêts ont évolué et se sont adaptées en fonction de ces conditions et processus naturels. Les pluies acides ont cependant sérieusement perturbé cet équilibre.

Degrés d'acidité

On mesure l'acidité d'une solution au moyen d'une échelle de pH. Il s'agit d'une échelle logarithmique, ce qui signifie que tout changement d'une unité dans l'échelle de pH correspond à un degré d'acidité dix fois plus élevé ou plus faible. Par conséquent, une solution dont le pH est de 4,0 est dix fois plus acide qu'une solution dont le pH est de 5,0 et cent fois plus acide qu'une solution dont le pH est de 6,0.

L'eau distillée, qui a un pH de 7,0, n'est ni acide ni alcaline. En raison de la présence de gaz carbonique dans l'atmosphère, le pH de la pluie est de 5,6 environ en l'absence de tout autre facteur.

Les précipitations dont le pH est inférieur à 5,6 sont appelées "précipitations acides"; toutefois, des quantités importantes d'acide proviennent également de dépôts secs de gaz et de particules. Dans presque tout le Sud de l'Ontario, le pH moyen de la pluie est d'environ 4,2. Dans la région éloignée du Nord-Ouest, le pH est en moyenne au-dessus de 5,0. La formation de dépôts acides étant plus importante dans le Sud de l'Ontario que dans le Nord, c'est dans cette partie de la province que l'on trouve le plus grand nombre de lacs acidifiés.

Étude des lacs

Il existe plus de 250 000 lacs en Ontario. D'après une étude récente, au moins 19 000 d'entre eux sont atteints par les pluies acides, notamment dans la région de Muskoka-Haliburton, grande région de tourisme et de villégiature.

La plupart des lacs ont la capacité de neutraliser une certaine quantité d'acide. Cette capacité se mesure au degré d'alcalinité découlant de la présence de bicarbonate dans l'eau. Si un lac a un degré élevé d'alcalinité, il peut résister aux arrivées d'acides, et donc ne pas changer de pH. On peut observer des baisses de pH dans les lacs à faible degré d'alcalinité à l'époque de la fonte des neiges ou lors de pluies abondantes, qui provoquent des arrivées d'acides considérables dans les lacs.

Un lac dont le degré d'alcalinité est de zéro ou moins est un lac acidifié. Les lacs qui ne sont pas alcalins présentent une acidité minérale. Il s'agit de lacs qui ont habituellement un pH de moins de 5,0 et, si l'on y trouve des poissons, ces derniers appartiennent à des espèces robustes et résistantes aux acides, comme la perche. À mesure qu'un lac s'acidifie, les espèces sensibles, dont l'achigan et l'omble, ne peuvent plus se reproduire; il se peut cependant que certains poissons adultes arrivent à survivre et meurent de vieillesse ou d'autres causes.

as limestone slowly dissolves. Alkalinity can also be generated in soils, so that groundwater and soil runoff inputs to some lakes can be an important supply of neutralizing capacity. In some cases, alkalinity levels can be reduced by naturally occurring acids. These acids are formed during the decomposition of leaves and other organic material. The presence of these acids is usually observed as a brown colouration in water, and can be quite noticeable in areas with extensive swamps or bogs.

While lakes and streams vary with respect to their pH, effects on aquatic life begin at around pH 6.0. Smaller organisms such as phytoplankton (microscopic plants), zooplankton (microscopic animals), insects and their larvae are affected not far below this level. As the pH of the lake falls gradually over time with increased acid loadings, larger life forms are affected. Crayfish are damaged at about pH 5.7. Spotted salamanders can lose 65% of their embryos at pH 5.0, and bullfrogs may lose all their eggs at pH 4.1. Most fish species cannot reproduce below pH 5.0. Some minnow species (e.g. fathead minnow, common shiner and pearl dace) disappear below pH 6.

Certain species may increase in number and size. For some this will be due to the elimination of their competition or predators. Others will flourish because they actually prefer more acidic conditions. Both are possible explanations for the excessive growth of acid tolerant filamentous algae in many lakes affected by acidification. This type of growth can affect fish and plant life by blocking sunlight and consuming oxygen in the water as well as swimming quality.

But the pH doesn't need to drop to lethal levels to affect or even eliminate many aquatic populations. Disruptions in the food web automatically affect the higher organisms which depend on the extinct populations for food, and younger organisms tend to be more acid-sensitive than adults. Eggs, embryos and young-of-the-year (newborn) fish are especially at risk at lower pH levels, and some fish species have been completely or all-but eliminated from lakes due to repeated loss of recruiting populations.

The release in unprecedented numbers of metal ions previously part of the underlying soil or rock into the water or soil solution is an effect of acid rain which has major implications for the environment. Many fish die of suffocation due to the clogging of their gills with excess aluminum ions or aluminum hydroxide released into the water.

Finally, *spring shock* occurs when sulphuric and nitric acids retained in snow are suddenly released into river and lake systems during the spring thaw, resulting simultaneously in a sudden drop in pH and an increase of aluminum ions. This toxic shock has sometimes resulted in mass kills of adult fish, but more commonly has drastic effects on the success of the spring hatching, with which it often coincides.

Examples of lakes with large amounts of acid neutralizing capacity are the Great Lakes, the Kawarthas, and lakes around the Rideau system. Lakes on the Canadian Shield typically have low acid neutralizing capacity. This region is underlain by granite, and has many exposed rock outcrops. Granite is insoluble and can supply little alkalinity. The soils are usually shallow and sandy or acidic. These acidic soils are not the result of acid deposition, but are formed by the decomposition of organic material such as forest litter. Runoff from these soils cannot contribute neutralizing capacity to lakes, so that most lakes on the Shield have low alkalinity levels.

The Ministry of the Environment, in co-operation with the Ministry of Natural Resources, conducts lake surveys to determine the sensitivity of Ontario lakes to acidic precipitation. This sixth summary of the results of this survey includes information on 6,722 lakes throughout the province, and is issued by the Ministry of the Environment as part of its Acidic Precipitation in Ontario Study (APIOS). This list is cumulative, so changes in the number of acidic lakes from previous brochures reflect new lakes that have been identified, rather than lakes turning acidic since the last listing was published.

The brochure presents an alphabetical list by county or district of the lakes sampled to date, with an indication of the relative sensitivity of each of the lakes to the acidification process. The table provides a summary of the number and percentage of lakes in each alkalinity class organized by county or district.

La capacité d'un lac à neutraliser les acides est fonction d'un certain nombre de facteurs. Les lacs qui sont situés dans des régions calcaires ont en général un degré élevé d'alcalinité, l'alcalinité provenant de la transformation lente du calcaire en bicarbonate. L'alcalinité peut aussi provenir d'eaux souterraines ou de ruissellements qui se déversent dans certains lacs et représentent une part importante de leur capacité à neutraliser les acides. Dans certains cas, le degré d'alcalinité peut également être réduit par des acides qui se forment naturellement au cours du processus de décomposition des feuilles et d'autres matières organiques. On remarque généralement la présence de ces acides à la coloration brune de l'eau, qui est particulièrement visible dans les régions où se trouvent de grandes étendues marécageuses.

Les lacs et les cours d'eau n'ont pas tous la même acidité, mais la vie aquatique est compromise quand le pH descend aux alentours de 6,0. Légèrement sous ce seuil, les petits organismes comme le phytoplancton (plantes microscopiques), le zooplancton (animaux microscopiques), les insectes et leurs larves sont affectés. Plus le pH diminue sous l'effet des charges acides, plus les gros organismes s'en ressentiront. À 5,7, l'écrevisse est atteinte. À 5,0, la salamandre tachetée perd jusqu'à 65 % de ses embryons, tandis que le ouaouaron risque de perdre tous ses oeufs à 4,1. Quand le pH est inférieur à 5,0, la plupart des poissons sont dans l'impossibilité de se reproduire. Certaines espèces de vairons (tête-de-boule, méné à nageoires rouges et mullet perle, par exemple) meurent quand le pH est inférieur à 6.

Certaines espèces verront leur nombre et leur taille augmenter, soit parce que leurs concurrents ou leurs prédateurs sont éliminés, soit parce qu'elles affectionnent les eaux acides, deux faits qui expliquent la prolifération d'algues filamenteuses résistantes dans bien des lacs acidifiés. Ces algues nuisent aux poissons et aux plantes, car elles bloquent le soleil et consomment l'oxygène. En outre, elles rendent les eaux impropres à la baignade et sont dangereuses, puisque les roches sont souvent glissantes à cause d'elles.

Le pH n'a pas besoin de baisser jusqu'à un niveau léthal pour atteindre ou même éliminer beaucoup de populations aquatiques. Toute perturbation de la chaîne alimentaire se répercute sur les organismes supérieurs qui s'alimentent des populations extinctes. Qui plus est, les jeunes comme les vieux individus sont plus sensibles à l'acidité que les adultes. Les oeufs, les embryons et les nouveau-nés sont particulièrement à risque quand le pH est bas, et des espèces de poissons ont été éliminées de certains lacs parce que le nombre d'individus aptes à se reproduire diminuait de plus en plus. D'autres ont été supprimées par le haut, les générations mourant à un âge toujours plus jeune avec les années.

Un nombre sans précédent d'ions de métaux qui faisaient partie du sous-sol ou du soubassement sont libérés dans la solution d'eau ou de terre. Voilà un effet des pluies acides qui a d'importantes conséquences pour l'environnement. Beaucoup de poissons meurent suffoqués, leurs branchies étant obstruées d'ions ou d'hydroxyde d'aluminium.

Enfin, un *choc printanier* se produit quand les acides sulfuriques et nitriques qui se trouvent dans la neige sont soudainement rejetées dans les rivières et les cours d'eau au moment du dégel. Le pH baisse tout à coup et le nombre d'ions d'aluminium s'accroît. Ce choc toxique a surtout provoqué des hécatombes de poissons adultes. Le plus souvent, toutefois, il nuit simplement au frai du printemps, avec lequel il coïncide.

Parmi les lacs qui ont une capacité élevées à neutraliser les acides, mentionnons les Grands Lacs, les Kawartha et les lacs du bassin de la rivière Rideau. Par contre, les lacs du Bouclier canadien n'ont généralement qu'une faible capacité à neutraliser les acides. Cette région a un sous-sol granitique et présente de nombreux affleurements rocheux. Le granit est insoluble et ne contribue pour ainsi dire pas à l'alcalinité des lacs. Les sols sont en général peu profonds et ils sont sablonneux ou acides. Leur acidité ne provient pas de dépôts acides mais de la décomposition de matières organiques comme c'est le cas, par exemple, des litières des forêts. Les ruissellements provenant de ces sols ne contribuent donc pas à accroître la capacité des lacs à neutraliser les acides, et c'est pourquoi la plupart des lacs du Bouclier canadien n'ont qu'un faible degré d'alcalinité.

Le ministère de l'Environnement, en collaboration avec le ministère des Richesses naturelles, effectue des études pour déterminer le degré de sensibilité des lacs de l'Ontario aux précipitations acides. Ce sixième rapport résume le résultat des analyses menées dans 6722 lacs de la province et il est publié par le ministère de l'Environnement dans le cadre

For example, 24.7% or 1660 of the lakes were found to be not sensitive to acidification, and a further 17.6% or 1185 lakes had low sensitivity. 37.8% or 2539 of the lakes, had moderate sensitivity, and 14.9% or 1002 lakes were extremely sensitive. Five per cent, or 336 lakes were classified as acidic.

Level 1 lakes have zero or negative alkalinity; they have already become *acidic*. Many or all fish species may be absent from such lakes. Clam, snail and many amphibian species may also be absent. Level 1 lakes, unless naturally high in organic color, are exceptionally clear. Clouds of algae may accumulate in inshore areas.

Level 2 lakes have very low alkalinity and are *extremely sensitive* to heavy acid loadings. Depressions in pH may occur during spring run-off, and algae clouds are also common in these lakes. These lakes are around pH6 and therefore are biologically damaged.

Level 3 lakes are *moderately sensitive* to heavy acid loadings. Fish and other biota are generally less at risk in comparison to level 2 lakes.

Level 4 lakes are of *low sensitivity* and have likely experienced no biological damage due to acid deposition.

Level 5 lakes are *not sensitive* to acid loadings and are capable of withstanding heavy acid loadings during spring run-off without biological damage. Such lakes contain sufficient buffering capacity to neutralize acid rain for an indefinite period of time.

Lake sampling and analysis is continuing, and up-dated listings will be published periodically.

de son Étude sur les précipitations acides en Ontario. Cette liste étant cumulative, les changements observés dans le nombre de lacs acidifiés comparativement aux publications précédentes reflètent l'ajout de nouveaux lacs et non l'acidification de lacs depuis la publication de la dernière liste.

Le présente bulletin contient une liste alphabétique des lacs analysés jusqu'à présent, répartis par comté ou district; le nom de chaque lac est suivi de l'indication de son degré de sensibilité au processus d'acidification. Il contient également un tableau qui précise le nombre et le pourcentage de lacs dans chaque catégorie d'alcalinité par comté et district.

Le tableau permet de constater, par exemple, que 1660 lacs, soit 24.7 pour 100 des lacs étudiés, ne manifestaient aucune sensibilité à l'acidification et que 17.6 pour 100 des lacs où 1185 lacs n'y étaient que peu sensibles. Par ailleurs, 2539 des lacs étudiés (soit 37.8 pour 100) étaient modérément sensibles et 1002 lacs (soit 14.9 pour 100) étaient très sensibles. Cinq pour cent des lacs étudiés, soit 336, étaient acidifiés.

Les lacs de niveau 1 ne sont pas alcalinis; il sont déjà *acidifiés*. De nombreuses espèces — et parfois toutes les espèces — de poissons en sont disparues. Les coques, les escargots et de nombreux amphibiens peuvent en être également absents. Sauf s'ils contiennent des matières organiques naturelles, les lacs de niveau 1 sont d'une limpidité remarquable. On trouve parfois des accumulations d'algues près des rives.

Les lacs de niveau 2 ont un degré d'alcalinité très bas et sont *très sensibles* aux arrivées importantes d'acides. Les ruissellements du printemps peuvent entraîner des baisses de pH et ces lacs ont fréquemment des algues. Ces lacs ont un pH d'environ 6 et sont donc biologiquement atteints.

Les lacs de niveau 3 sont *modérément sensibles* aux arrivées importantes d'acides. Les poissons et autres êtres vivants courent généralement moins de risques que ceux des lacs de niveau 2.

Les lacs de niveau 4 sont *peu sensibles* et le milieu biologique n'a en général pas été endommagé par les dépôts acides.

Les lacs de niveau 5 sont *insensibles* aux dépôts acides et peuvent absorber d'importantes quantités d'acides lors des ruissellements du printemps sans subir de dommages biologiques. La capacité tampon de ces lacs leur permet de neutraliser les pluies acides indéfiniment.

Les travaux d'échantillonnage et d'analyse se poursuivent et le ministère en publiera périodiquement les résultats.

LAKES SURVEYED FOR ACID SENSITIVITY

Lakes are listed according to county/district. In some cases, commonly used alternate lake names are also given in brackets after the name normally used on maps.

The number following the lake name indicates degree of sensitivity to acidification as follows: (1) acidic, (2) extreme sensitivity, (3) moderate sensitivity, (4) low sensitivity, (5) not sensitive.

Township (Tp) locations are also in brackets for all lakes where the information is available.

LAC ÉTUDIÉS POUR LEUR SENSIBILITÉ AUX DÉPÔTS ACIDES

Les lacs sont énumérés par comté ou district. Dans certains cas, si un lac est connu sous au autre nom, celui-ci figure entre parenthèses après le nom qui lui est donné sur les cartes.

Le chiffre qui suit le nom du lac indique le degré de sensibilité à l'acidification : (1) acidifié, (2) très sensible, (3) modérément sensible, (4) peu sensible, (5) insensible.

Le canton dans lequel se trouvent les lacs est aussi indiqué entre parenthèses si ce renseignement est connu.
